EVENTFLOW AI

Updated Product Requirements Document (PRD)

---

1. Introduction

EventFlow AI is an AI-powered event planning and business management platform designed to streamline communication, proposal preparation, business approval and customer decision-making.

During the Preliminary Round, EventFlow AI primarily demonstrated the concept of AI-assisted event planning through separate customer and business interfaces.

Following the Preliminary Round, the team focused on strengthening the connections between the two portals, improving database integration, refining business workflows and increasing the reliability of the overall system.

The Final Round version places greater emphasis on practical SME operations, human approval, data consistency and a complete end-to-end customer journey.

2. Summary of Major Changes

No.	Component	Changes Since Preliminary Round
1	Business Overview	Improved dashboard navigation and linked KPI cards to relevant business pages
2	Requests Management	Strengthened Supabase integration and customer request visibility
3	Proposal Management	Connected AI proposals, Business approval and Customer selection through Supabase
4	Approval Management	Introduced a dedicated Approvals page to separate approval tasks from proposal management

5	Events and Availability	Improved the connection between event records and calendar availability
6	Customer Portal	Refined Plan A/B selection and confirmation; removed incomplete Change Request functionality
7	Authentication	Improved Customer/Business role separation and administrative account approval
8	Dashboard Analytics	Improved request-related indicators using available database information
9	Interface Reliability	Addressed page remounting, refresh behaviour and development-oriented UI messages
10	AI Generation	Strengthened quota management and controlled paid AI usage
11	Data Transparency	Clearly distinguished synthetic supplier, event and reporting data
12	Testing and Deployment	Expanded regression testing, build verification and GitHub version control

---

3. Detailed Functional Enhancements

3.1 Business Portal — Interactive Overview Dashboard

Preliminary Round

During the Preliminary Round, the Business Portal Overview served mainly as a dashboard for displaying business statistics and providing a general summary of event planning operations. The dashboard contained indicators such as open requests, pending approvals and event information. However, the interaction between these dashboard indicators and their corresponding management

pages was limited. Users primarily relied on the sidebar navigation to access individual business functions.

Final Round Improvements

The Overview Dashboard was refined to support more direct navigation between business information and the relevant management pages. Key performance indicator (KPI) cards were enhanced to act as navigation entry points.

Open Requests

The Open Requests card displays the number of requests requiring business attention. Selecting the card provides direct access to the Requests page, where business users can review customer submissions and related information.

Recently Updated Requests

The previous general update indicator was replaced with a more specific Recently Updated Requests metric. The updated indicator was designed to use request modification timestamps from Supabase to identify requests changed within the previous seven days. This provides a more meaningful measure of recent customer activity than a general count of requests or proposals.

Events

The Events indicator provides access to event-related information, supporting navigation between the Overview and event management functions.

Awaiting Approval

The Awaiting Approval indicator directs business users toward the proposal approval workflow, reducing the number of steps needed to review pending proposals.

Reason for Change

The previous dashboard primarily displayed information, whereas the updated dashboard is intended to support faster operational decision-making. For event planning SMEs, employees frequently need to move between incoming requests, proposal reviews and scheduled events. Direct navigation reduces unnecessary page switching and helps business users prioritize their work.

Expected Benefits

- Faster access to important business functions.
- Reduced navigation effort.
- Improved visibility of incoming requests.
- More efficient proposal review.
- Better user experience for SME employees.

3.2 Business Portal — Customer Request Management and Supabase Integration

Preliminary Round

The Preliminary Round demonstrated customer request submission and the display of request information through the Business Portal. However, the connection between submitted customer information and the business-facing interface required further refinement and verification. Some development-stage views also included seeded demonstration records.

Final Round Improvements

Customer requests are stored in Supabase and retrieved by the Business Portal. The updated Requests page supports the display of customer-submitted information, including event names, event requirements and related request details. Request headings were also improved to provide clearer identification. For example, instead of displaying only a customer username, the interface can display:

Reason for Change

An event planning business may receive multiple requests from different customers. Displaying only customer usernames can make request identification difficult, especially when the same customer submits multiple events. Integrating request data with Supabase improves consistency between customer submissions and business operations.

Expected Benefits

- Clearer identification of customer requests.
- Better organization of event requirements.
- Reduced manual searching.
- More consistent information between portals.
- Improved request management efficiency.

3.3 Proposal Management — Connected Customer Selection and Business Approval

Preliminary Round

The Preliminary Round introduced AI-assisted proposal generation using RunPod-hosted Qwen3-8B. The system was designed to generate two alternative event plans, Plan A and Plan B, based on customer requirements. The initial implementation demonstrated proposal generation and review concepts, but the persistence and coordination of downstream approval and customer selection required further development.

Final Round Improvements

The proposal workflow was strengthened through Supabase integration. AI-generated Plan A and Plan B proposals are represented as database records linked to their corresponding customer requests. The Business Portal retrieves proposal information for review, while the Customer Portal displays proposals released for customer consideration.

The updated workflow supports the following stages:

Stage 1 — Customer Request

The customer submits event requirements through the Customer Portal.

Stage 2 — AI Proposal Generation

RunPod-hosted Qwen3-8B generates Plan A and Plan B based on the customer's requirements.

Stage 3 — Business Review

Business personnel examine the proposed event concepts, services, timelines and estimated costs.

Stage 4 — Business Approval

Business personnel approve the proposals for customer review through the relevant approval workflow.

Stage 5 — Customer Selection

The customer compares the approved proposals and selects the preferred plan.

Stage 6 — Customer Confirmation

The customer's selection is recorded in Supabase and reflected through the corresponding proposal or request status. The Final Round implementation also refined proposal status handling and the display of customer-selected plans within the Business Portal.

Reason for Change

The Preliminary Round emphasized the ability of AI to generate event planning recommendations. However, AI generation alone does not complete a business transaction. Event planning SMEs must review estimated costs, evaluate feasibility and authorize proposals before presenting them to customers. Connecting business approval and customer selection creates a more practical workflow that combines AI assistance with human decision-making.

Expected Benefits

- Improved coordination between Customer and Business Portals.
- Reduced reliance on manual proposal communication.
- Clearer proposal status tracking.
- Stronger human oversight of AI-generated recommendations.
- Better consistency between customer decisions and business records.

3.4 Business Portal — Dedicated Approvals Page

Preliminary Round

Proposal review and approval were primarily associated with the Proposal Management interface. Business users needed to manage proposal information and approval-related tasks within the broader proposal workflow.

Final Round Improvements

A dedicated Approvals page was introduced to provide a clearer separation between proposal management and approval decision-making. The Proposal Management page focuses on displaying and reviewing proposal information, while the Approvals page provides a dedicated location for approval-related tasks. This allows business users to distinguish between reviewing proposal content and making an authorization decision. The Overview Dashboard also includes an Awaiting Approval indicator to support faster navigation to the approval workflow.

Reason for Change

Separating approval responsibilities from general proposal management improves workflow organization. Business personnel can identify proposals requiring a decision without searching through unrelated proposal records. The dedicated approval interface also supports the human-in-the-loop approach required for responsible AI-assisted business automation.

Expected Benefits

- Clearer division of business tasks.
- Easier identification of proposals requiring approval.
- Improved review efficiency.
- Better support for human decision-making.
- More organized Business Portal navigation.

Technical Verification Requirement: The Final Round must verify that proposal release is restricted through backend or database authorization, and that rejection prevents unauthorized release.

3.5 Events Management and Availability Calendar Integration

Preliminary Round

The Preliminary Round included event management and availability concepts as part of the Business Portal. Event information and scheduling features were presented as separate business functions.

Final Round Improvements

The Events and Availability interfaces were refined to provide a more connected view of event information and scheduling. The Events page presents event records and related details. The Availability page provides a calendar-based interface for viewing event reservations and date availability. The updated implementation supports the presentation of event information across these related business views, with Supabase-backed event records used where supported. Calendar views also distinguish demonstration events from application records. Existing restrictions on unavailable event creation or editing functions remain in place.

Reason for Change

Event planning SMEs must consider scheduling and event availability when managing bookings. Separating event details from scheduling information can increase the effort required to understand business commitments. A more connected Events and Availability interface improves visibility of upcoming activities and supports better scheduling awareness.

Expected Benefits

- Improved visibility of event schedules.
- Easier access to event-related information.
- Better coordination between event management and calendar views.
- Reduced confusion over event availability.
- Improved preparation for future booking management capabilities.

3.6 Customer Portal — Improved Proposal Selection and Confirmation

Preliminary Round

The Customer Portal supported event request submission and the intended ability to compare AI-generated event proposals. The original workflow also included a Change Request feature intended to allow customers to request revisions and trigger further AI generation.

Final Round Improvements

The proposal selection and confirmation workflow was refined to support customer decisions using saved proposal records. Customers can review approved Plan A and Plan B proposals and select their preferred option. The Customer Portal also displays the corresponding proposal status and confirmation information. The Change Request section was removed from the customer-facing interface because the revision process was not reliably connected to AI regeneration. The removal included the Change Request form, submission controls and customer-facing revision history. Existing backend logic and stored historical records were preserved.

Reason for Change

The team prioritized a complete and reliable customer selection process over retaining an unfinished revision feature. An incomplete Change Request function could confuse customers and introduce additional failure points during the Final Round demonstration. Removing it simplifies the customer journey and keeps the product focused on its operational core.

Expected Benefits

- Simpler customer experience.
- More reliable proposal selection.
- Reduced workflow complexity.
- Clearer customer decision-making.
- Improved readiness for end-to-end demonstration.

3.7 Authentication, User Roles and Administrative Approval

Preliminary Round

The system included Customer and Business Portal access as part of the proposed platform architecture. The team identified the need to distinguish between customer-facing and business-facing responsibilities.

Final Round Improvements

The authentication and role-management workflow was strengthened through Supabase Authentication and application-level access controls. The system supports separate Customer and Business account experiences. Business account access includes an administrative approval process. New Business accounts can be restricted from accessing authorized business functions until the appropriate administrative approval is granted. The Business Portal also includes an Admin Approvals interface for account-related approval tasks. This is separate from the proposal approval workflow.

Reason for Change

Business management functions may involve customer information, commercial proposals and approval decisions. Allowing unrestricted access to these functions would create security and accountability risks. Role separation and administrative approval help ensure that business functions are accessed by appropriate users.

Expected Benefits

- Improved access control.
- Clearer separation of user responsibilities.
- Reduced unauthorized access risk.
- Better account administration.
- Stronger foundation for secure SME operations.

3.8 Business Portal — Interface Stability and User Experience

Preliminary Round

During development, some Business Portal pages experienced interface refresh and navigation issues. These included page flickering and repeated remounting when background data refreshes occurred.

Final Round Improvements

The Business Portal code was reviewed and refactored to improve component stability. The team addressed problematic rendering patterns associated with route components and repeated background refreshes. The interface was also refined by removing unnecessary development messages and simplifying technical terminology. Routine messages referring to Supabase loading, internal

implementation phases and development-only functionality were reduced or removed where appropriate. Useful loading indicators and error messages were retained.

Reason for Change

An SME platform must remain understandable and stable during normal use. Repeated interface remounting can interrupt navigation and reduce user confidence. Removing development-oriented messages also makes the application more suitable for nontechnical business users.

Expected Benefits

- Smoother navigation.
- Improved interface consistency.
- Reduced user confusion.
- Better presentation quality.
- Improved usability for business personnel.

3.9 Dashboard Analytics and Reporting Improvements

Preliminary Round

The Business Portal included dashboard statistics and reporting visualizations to demonstrate potential business insights. Some reporting values were based on seeded or illustrative information.

Final Round Improvements

The dashboard was refined to present more specific operational indicators. The Recently Updated Requests metric was designed around request modification activity rather than a general update count. The Reports interface was also updated to distinguish illustrative charts from verified business performance information. Sample supplier and event data were more clearly labeled.

Reason for Change

Business dashboards should help users interpret operational information accurately. Unlabeled synthetic figures could create misleading impressions about actual business performance. The refinements improve transparency and help users distinguish real application activity from illustrative information.

Expected Benefits

- More meaningful operational indicators.
- Clearer interpretation of dashboard statistics.
- Improved reporting transparency.
- Reduced risk of misrepresenting synthetic data.

3.10 AI Generation Management and Cost Control

Preliminary Round

EventFlow AI used RunPod-hosted Qwen3-8B to support AI-generated event proposals. Because AI generation involves external computing resources, the system required controls to limit unnecessary usage and associated costs.

Final Round Improvements

The AI generation system was strengthened with Redis-based quota management. The total generation quota was extended to 50 attempts through a guarded, one-time operation.

At the last verification, the ledger recorded:

- Total allowed attempts: 50
- Previously consumed attempts: 20
- Remaining attempts: 30

The extension preserves historical usage and prevents the quota from being reset through repeated extension attempts. Additional automated tests were introduced to validate quota limits, extension rules and reservation behaviour.

Reason for Change

The team needed additional capacity for Final Round testing while maintaining control over paid AI generation. A finite quota reduces the risk of uncontrolled external API usage and unexpected costs.

Expected Benefits

- Better AI cost management.
- Additional testing capacity.
- Preserved usage history.
- Improved operational safeguards.
- More predictable resource consumption.

The quota increase does not automatically enable live AI generation; deployment settings and generation safeguards remain separate.
